### Abstract

In the past with a person who wore eyeglasses and had to be on oxygen at the same time, usually that person would have to wear the arms from the eyeglasses and the airtube that carries the oxygen to their nose on their ears simultaneously..

What I'm proposing is , combine eyeglass frames and the tube that carries the oxygen together. How that would be done is, making the eyeglass frames hollow, starting from the arms of the glasses, around the eye pieces, down below to the nipples that would connect to the nose piece, and finally in the nostrils.

With this combination a person could wear glasses and breath with the oxygen at the same time with more ease. That makes for less adjustment, and it's much less frustrating than the old way.
